ABSTRACT

Objective: Skin is the largest protective organ of body between external and internal environment. The various causes of skin diseases are consumption of unhealthy food or lifestyle modification or due to stress, skin disease are increasing day to day. Methods: Based on the symptom of various Kushtaroga mainly mahakustha a comparative study is done with the skin disease of modern science. Result: A wide range of similarity was found between the 7 types of kustha and with the various dermatological disorders as such kapalakustha with scleroderma; richyajivyha with Lichen Planus and the other are also compared as such. Conclusion: A concise differential diagnosis and identification of these disorders are actually difficult for a non dermatologist because he or she is not well versed in recognition of cutaneous lesions or their spectrum of presentation. Thus in the present study an attempt has been made to compare the various mahakustha mentioned in Ayurveda with its nearest possible modern counterpart and to elaborate it for better understanding.

Keywords: Mahakustha, Skin disorder, Ayurveda

INTRODUCTION

Skin is the largest protective organ of the body between external environment and internal environment. It is a minor that reflects physiological, pathological, metabolic condition of the body and help in diagnosis of disease. In Ayurveda twach is the first line of defence of the body. In Ayurveda the disease which manifest in the seven layers of twach are considered as twakaroga which involve twaka, rakta, mamsa, lasika. Ayurvedic classification i.e. mahakustha, khudrakustha, khudraroga are all included in obstinate skin diseases in modern science. A total of 18 kushtaroga has been mentioned in our brihatrayee of which 7 are mahakustha and 11 are kshudrakustha. All the kusthas have some specific mark of identification and for a non-dermatologist it becomes almost impossible for the proper diagnosis. So in this paper an attempt has been made to find out the specific
character found in that particular Mahakustha and also a co-relation has been made with the modern counterpart for easy understanding. The description of the 7 types of Mahakustha is as follows:

i) **Kapala Kustha:**
The patches in the skin look like black and reddish pieces of kapala which are ununctuous rough and thick to touch and are associated with excessive pain.\(^1\) It can be compared to scleroderma, the first specific clinical symptoms to suggest a diagnosis of scleroderma is skin thickening that begins as swelling or puffiness. Later the skin becomes hard, shiny and leathery and hardens like a stone.\(^2\)

ii) **Audumbara Kustha:**
These types of Kustha is associated with burning sensation, itching, pain and redness all around and the hair on the patches become brown in colour and looks like the fruit of udumbara.\(^3\)This can be compared with boil/furuncle. Usually associated with red follicular nodules which become necrotic and discharge their central core also associated with pain & itching.\(^4\)

iii) **Mandala Kustha:**
They are red & white in colour. It is stable, compact, untuous and circular in shape with elevated patches, difficult to cure and the patches are mated with each other.\(^5\) This Mandala Kustha can be compared with Psoriasis, in psoriasis also there are deep pink to red colour erythematosus elevated patches and often surrounded by hypo pigmented halo. Lesions are surmounted with loose, lamellar, silvery white scales.\(^6\)

iv) **Risyayivha:**
It is rough, red in edges and brown inside and it is painful which resemble the tongue of a rsya (a type of antelope)\(^7\). It can be compared with Lichen Planus, which are very itchy, violaceous, shiny, flat topped, polygonal papules of variables sizes.\(^8\)

v) **Pundarika:**
It is white in colour with red edges, it resemble the leaf of lotus, elevated and accompanied with burning sensation.\(^9\) May be compared with Urticaria, where itching is prominent in superficial wheals, lesions begin as erythematous macule while rapidly evolve into pale pink oedematous wheals with a surrounding flare.\(^10\)

vi) **Siddhama:**
Usually siddhama Kustha is white and coppery in colour, thin, when rubbed emits small particles of the skin in from of dust resembling the flowers of alabu.\(^11\) This can be compared to Pityriasis Versicolor which are hypo pigmented, scaly perifollicular macules, lesions appear to be sitting on the skin surmounted with branny scale which can be accentuated by scratching lesions gently.\(^12\)

vii) **Kakana:**
It is red in colour like seeds of gunja and it is very painful and does not get suppurated, all three dosas get vitiated and is incurable.\(^13\) This can be compared c Squamous cell carcinoma having ulcer with everted edges or ulcer with red granular floor. Induration & fixity to underlying tissue.\(^14\)

**DISCUSSION**

KapalaKustha caused by the predominance of vatadosha and thus characterised by arunavarna, ruksha (rough), parusha (thick) to touch and becomes like pieces of kapala (pot). Kapala is better compared with scleroderma which has the symptoms similar like hard, shiny and hard like a stone.
Udumbara Kustha is having pitta predominance characterised by daha burning sensation, ruja (pain) and the change in colour of the hairs so being compared with furuncle which is associated with pain and itching along with red follicular nodules which comes out of hair follicle. Mandala Kustha compared with psoriasis for both have pale red to red colour erythematous elevated patches usually Mandala kustha is dominated with Kaphadoshas and thus are snigdha, sthira. The roughness of risyajivha is attributed to vata and (red edges) arunavarna and ruja (pain) is attributed to pitta dosha, this can be better compared with lichen planus for having a violaceous shiny, itchy skin. The reddish white patches are the clinical manifestation of Pundarika. The burning sensation along with redness is due to pittadosha with similar features found in urticaria with erythematous macule of pale pink colour. In Siddhmakusthadoshas involved are vata and kapha which emits small particle of skin in from of dust this is compared with branny scales which is accentuated by scratching gently. The last out of the seven mahakustha is the Kakana which has the characteristics of all three dosas which is red in colour like gunja flower and having excessive pain and burning sensation. In squamous cell carcinoma also we find thick verrucous cauliflower like plaque on raised ulcer with red granular floor. Kakana is considered as incurable and so is compared with squamous cell carcinoma.

CONCLUSION

In the present study an attempt has been made to compare the 7 types of MahaKustha which are mentioned in Ayurveda with that of the modern science. Quiet a similarity has been found from the clinical features point of view. Thus, kapala being compared with Scleroderma, Audumbara with furuncle, Mandala Kustha with psoriasis. Risyajivha with lichen planus, Pundarika Kustha can be compared to Urticaria, Siddhama with pityriasis Versicolor and Kakanak with Squamous Cell carcinoma
